Applied Statistical Programming - Spring 2022

Problem Set 3

Due Wednesday, March 2, 10:00 AM (Before Class)

Instructions

- 1. The following questions should each be answered within an R script. Be sure to provide many comments in the script to facilitate grading. Undocumented code will not be graded.
- 2. Work on git. Fork the repository found at https://github.com/johnsontr/AppliedStatisticalProgramming2022 and add your code for Problem Set 3, committing and pushing frequently. Use meaningful commit messages because these will affect your grade.
- 3. You may work in teams, but each student should develop their own Rmarkdown file. To be clear, there should be no copy and paste. Each keystroke in the assignment should be your own.
- 4. For students new to programming, this may take a while. Get started.

Let's Make a Deal¹

In the game show "Let's Make a Deal', the candidate gets to choose one of three closed doors, and receives the prize behind the door they choose. Behind one door is a new car; behind the other two doors are goats. After the contestant selects one of the 3 doors, the host opens one of the other two doors, and reveals a goat. Now, the candidate has the option of either sticking with the door they originally selected, or switching to the only other door that is still closed. What should the candidate do, and why? What are the probabilities of winning the car if they stay versus if they switch? This question is known as the Monty Hall Problem.

Your tasks

For this problem set, you will not solve the Monty Hall Problem, but you will have to code a slightly simplified version of the "Let's Make a Deal" game. More specifically, you will set up a new class, which contains information regarding the door a player chooses, and a method that simulates a modified version of the game. You will have to do this using the S3 class system. Here are the specific instructions:

- 1. Define a new class: door. Objects of this class simply take on one numeric value: 1, 2, or 3 indicating which door a candidate chooses.
- 2. Create a method for door objects that is called PlayGame. This method is supposed to do the following:
 - take the numeric value that is stored in the door object,
 - draw a random number between 1 and 3 that presents the door behind which the car is hidden,
 - compare the two numbers, and print a message congratulating a winning candidate that chose the correct door, or expressing sympathies for a losing candidate that chose the wrong door.

 $^{^{1}} https://en.wikipedia.org/wiki/Let's_Make_a_Deal$

3. Write:

- a construction function that allows the user to create a door object,
- and a validation function that checks whether the value stored in door is actually an integer

```
door_fun <- function(x) {</pre>
    allowable_input <- x %in% c(1, 2, 3)
    # Assigning a vector to allowable input numbers
    if (!allowable_input) {
        stop("You didn't enter a door number that exists!")
    }
    # This tells user that input isn't a valid door number. Alma helped me out
    # with this one because the original function would get messy very fast.
    door_number <- as.integer(x)</pre>
    # Stores input as integer
    class(door number) <- "door"</pre>
    return(door number)
}
# Creating door selection function.
test_success <- 2
door_fun(test_success)
## [1] 2
## attr(,"class")
## [1] "door"
# Testing for success.
door validator <- function(x) {</pre>
    door_errors <- is.integer(x) & any(x %in% as.list(c(1, 2, 3)))</pre>
    # Check that the thing you input both an integer and either 1,2, or 3.
    if (door_errors) {
        return(x)
        # if the above is satisfied, just return the input.
    } else {
        stop("You didn't pick a door that was either between 1 and 3 or you didn't select an integer...
    # if the above is not satisfied, return the error.
}
# Notice that if we store the result from the construction function, it will be
# turned into an integer. So, if we were to, say, run 2.5 in the constructor,
# saved the output into an object, and passed that object through the validator
# function, we would not get an error since the object is now an integer. If we
# wanted to test the validator, then we would just input 2.5.
door_fun(test_success)
## [1] 2
## attr(,"class")
## [1] "door"
```

Testing for success.

```
PlayGame <- function(x) {
    UseMethod("PlayGame")
}

PlayGame.door <- function(door) {
    correct_door <- sample(3, 1)
    # Telling the function to take a sample from 1 to 3.
    if (door == correct_door) {
        print("You won!")
        # If what you input is the same as the random sample, print a winning
        # message.
    } else {
        print("Better luck next time...")
        # If what you input is not the same as the sample, print a losing
        # message.
    }
}</pre>
```

PlayGame.door(test_success)

[1] "Better luck next time..."
